THE PATENTS ACT 1990

PROVISIONAL SPECIFICATION FOR THE INVENTION ENTITLED

"ATTACHMENT SYSTEM"

The present invention will be described in the following statement:

TITLE

“ATTACHMENT SYSTEM”

FIELD OF THE INVENTION

5 The present invention relates to an attachment system, particularly intended for the attachment of ground engaging tools to the lip plate of mechanical digging devices.

Many mining and earthmoving operations require the use of mechanical digging devices, such as front-end loaders. Such mechanical digging devices commonly feature buckets which can be manipulated by a user to dig into earth or rocks to be
10 shifted. These buckets include a lip plate across the bucket floor. On this lip are mounted a series of ground engaging tools having a tooth-like appearance. These tools, in use, penetrate into the material being dug, and provide a leading edge for the bucket to follow.

The ground engaging tools are highly susceptible to wear due to the high level of
15 friction generated by their use. Accordingly, it is often desirable to be able to remove a worn ground engaging tool and substitute a new tool.

A common method of attachment for ground engaging tools is that of welding. In practice, however, a welded ground engaging tool can be difficult to replace without substantial dismantling of the bucket.

20 Mechanical methods of attaching ground engaging tools through the use of restraining bolts and pins have been proposed. These methods are often difficult to use in practice, as the forces generated against a ground engaging tool can cause deformation of the bolt or pin, thus making subsequent disengagement difficult.

The present invention attempts to overcome at least in part some of the aforementioned disadvantages of previous attachment system for ground engaging tools.

5

SUMMARY OF THE PRESENT INVENTION

In accordance with one aspect of the present invention there is provided an attachment system for connecting a first member to a second member, characterised in that the first member has a lug connected thereto, and the second member has an aperture arranged, in use, about the lug and wherein a clamping member is disposed between
10 the lug and the second member, the clamping member including a resilient portion such that the supply of a compressive force to the resilient portion acts to restrain disengagement of the second member from the lug.

BRIEF DESCRIPTION OF THE DRAWINGS

15 The present invention will now be described, by way of example, with reference to the accompanying drawings, in which:

Figure 1 is a perspective view of a ground engaging tool arranged to be attached to a lip plate (a portion of which is shown) in accordance with the present invention;

Figure 2 is perspective view of the underside of the ground engaging tool of Figure 1;

20 Figure 3 is a perspective view of the ground engaging tool and lip plate portion of Figure 1, shown during attachment, together with a clamping member in accordance with the present invention;

Figure 4 is a cross sectional view of a portion of the ground engaging tool and lip plate showing the clamping member of Figure 3, and showing a stabilizing member; and

Figures 5 to 8 are sequential cross sectional views of the arrangement of Figure 4
5 shown during the attachment process;

DESCRIPTION OF THE INVENTION

Referring to the Figures, there is shown a ground engaging tool 10 arranged to be attached to a portion of a lip plate 12. The lip plate 12 is substantially rectangular in
10 cross section, and extends around the rim of a bucket (not shown) of a mechanical digging device. The lip plate 12 includes an upper face 14, a lower face 16 and an end face 18. A tapered surface 20 extends from the end face 18 of the lip plate 12 to the upper face 14.

The lip plate 12 includes a lug 22 affixed by suitable means (for instance welding) to
15 the upper face 14. The lug 22 includes an elliptical prism portion 24 oriented towards the end face 18 of the lip plate 12, a top face 26 substantially parallel to the upper face 14 of the lip plate 12, a tapered surface 28 extending from the edge of the top face 26 to the edge of the elliptical prism portion 24 and a substantially flat rear face 30 oriented substantially perpendicularly to the upper face 14. The drawings show a weld
20 31 about the lug 22.

The ground engaging tool 10 comprises a leading edge 32, a first base portion 34 extending substantially perpendicularly of the leading edge 32, a front portion 36 extending away from the leading edge at a shallow angle, a second base portion 38 extending away from the first base portion 34 at a shallow angle, a transverse recess

40 disposed oppositely the leading edge 32 and an attachment portion 42. The front portion 36, leading edge 32 and the first base portion 34 co-operate to form a substantially V shaped working portion in order to penetrate, in use, the material being dug. The transverse recess 40 is complementary in shape to the lip plate 12, and
5 allows the ground engaging tool 10 to be located on the perimeter of the lip plate 12 adjacent the end face 18. The second base portion 38 tapers from the first base portion 34 in a direction away from the leading edge 32, and ends, in use, adjacent the lip plate 12. The leading edge 32, first and second base portions 34 and 38 and the front portion 36 define a working portion of the ground engaging tool 10.

10 The attachment portion 42 extends from the front portion 36 adjacent the recess 40 in a direction away from the leading edge 32. It locates, in use, along the upper face 14 of the lip plate 12, and co-operates with the lug 22.

The attachment portion 42 has a substantially flat lower surface 44, a substantially flat upper surface 46 and a rear surface 48. The attachment portion 42 includes an
15 engaging recess 50 extending inwardly of the rear surface 48 through a rear aperture 52 in the rear surface 48, and upwardly of the lower surface 44 through a lower aperture 45. The engaging recess has a first portion 54 remote from the rear aperture 52, and a second portion 56 adjacent the rear aperture 52. The first portion 54 is complementary in shape to the lug 22, whereas the second portion 56 is of larger
20 transverse dimension than the first portion 54. This allows, in use, the second portion 56 to be placed about the lug 22. This in turn allows the attachment portion 42 to be slid over the lug 22 in a longitudinal direction, and to locate in a position whereby the lug 22 is within the first portion 54 of the engaging recess 50. In this position relative

movement of the attachment portion 42 and the lip plate 12 in a transverse direction is restricted.

The attachment portion 42 further includes an aperture 58 within the upper surface 46.

The aperture 58 communicates with the second portion 56 of the engaging recess 50.

- 5 When the ground engaging tool is located such that the front of the lip plate 12 is engaged in the transverse recess 40 and the lug 22 is within the first portion 54 of the engaging recess 50, the aperture 58 is situated adjacent the rear face 30 of the lug 22.

The attachment system further includes a clamping member 60. The clamping member (60) as shown in Figures 3 to 8.

- 10 The clamping member 60 is of complementary cross sectional shape to the second portion 56 of the engaging recess 50 and has a first side 64 which is arranged to locate adjacent the lug 22 and a second side 66 opposite the first side 64. The second side 66 is arranged to locate adjacent the rear aperture 52. The clamping member 60 further includes side surfaces 67 and a top surface 68.

- 15 The clamping member 60 includes a recessed edge 70 extending between the first side 64 and the top surface 68. The recessed edge 70 is arranged to be complementary in shape to a lip 72 extending from the upper portion 46 of the attachment member 42 partially above the second portion 56 of the engaging recess 50.

- The clamping member 60 includes a substantially cylindrical chamber 80 extending
20 within the clamping member 60 from the first side 64 to a rear wall 82.

The clamping member 60 further includes a substantially cylindrical lug engaging member 62. The lug engaging member 62 is substantially complementary in shape to, and contained within, the chamber 80. An outer portion 63 of the lug engaging member 62 extends from the first side 64 of the clamping member 60.

A resilient annular member such as an O-ring 65 is located within an groove about the chamber 80 adjacent the first side 64 of the clamping member 60.

The lug engaging member 62 includes a substantially cylindrical recess 81 extending inwardly of the lug engaging member 62 from a rear end of the lug engaging member 62 adjacent, in use, the rear wall 82 of the chamber 80.

A resilient portion 90 such as a compressible spring is located within the recess 81. In the embodiment of the drawings the resilient portion 90 comprises a plurality of Belleville type cylindrical washers, however it will be appreciated that other resilient elements such as coil springs, rubber or resilient plastic elements could be used.

A substantially cylindrical slot 110 extends from the chamber 80 adjacent a rear end of the lug engaging member 62 to the second side 66 of the clamping member 60. The slot 110 is internally threaded.

The attachment system further includes a stabilizing member 98. The stabilizing member 98 is in the form of a prism, having front and rear faces 100, 102 which are substantially the same shape as the cross sectional shape of the second portion 56 of the engaging recess 50.

The stabilizing member 98 has a similar width to the lip 72 of the attachment portion 42.

The stabilizing member 98 has a substantially cylindrical aperture 112 which is arranged to locate, in use, adjacent the slot 110 of the clamping member 60 so as to form a single cylindrical passageway. The cylindrical aperture 112 may be threaded.

A compressing member in the form of a substantially cylindrical bolt 114 is arranged, in use, to locate within the passageway formed by the slot 110 and the aperture 112. The bolt is externally threaded, and is arranged to engage with the internally threaded

slot 110. The bolt acts to hold the stabilizing member 98 relative to the clamping member 60 during use.

The use of the clamping member 60 will now be described.

The attachment portion 42 is positioned over the lip plate 12 with the lug 22 located
5 within the first portion 54 of the engaging recess 50.

The clamping member 60 is then introduced through the aperture 58. When the clamping member is within the engaging recess 50 it is slid forward relative to the attachment portion 42 such that the recessed edge 70 is engaged by the lip 72. The clamping member 60 may be provided with channels 69 provided in the side surfaces
10 67. The channels 69 are arranged to cooperate with side lugs 71 within the second portion 56 of the engaging recess 50 in order to define a track along which the clamping member is slid within the engaging recess 50. In this way the outer portion 63 of the lug engaging member 62 is adjacent the rear face 30 of the lug 22.

The stabilizing member 98 is then introduced between the second side 66 of the
15 clamping member 60 and the rear aperture 52.

The clamping member is activated as follows. The bolt 114 is introduced into the passage created by the slot 110 and the aperture 112, and is threadedly engaged with the slot 110. When the bolt 114 is fully within this passage, the end of the bolt 114 is adjacent the resilient portion 90. The application of a turning force to the bolt so as to
20 promote the advance of the bolt into the recess 81 provides a compressive force on the resilient portion 90.

The effect of the compressive force on the resilient portion 90 is to cause lug engaging member 62 to apply a compressive force against the rear face 30 of the lug 22. In this way a compressive force is applied between the lug 22 and the attachment

portion 42, thus locking the ground engaging tool 10 in position relative to the lip plate 12.

When it is desired to remove the ground engaging tool 10 from the lip portion 12, the bolt 114 is unscrewed from the slot 110, thus releasing the compressive force from the resilient portion 90 of the lug engaging portion 62. The attachment portion 42 can then be readily removed from the lip portion 12 in the reverse of the above process, potentially allowing some members to be reused.

Modifications and variations as would be apparent to a skilled addressee are deemed to be within the scope of the present invention.
